Wrocław, 9-12.10.2019

arXiv:1905.00667

Experimental searches for CP

- ▶ Heavy ion collisions → Allow to probe different regions of QCD phase diagram
- ▶ Baryon number fluctuations \sim Proton number fluctuations
- ▶ Non-monotonic \sqrt{s} dependence of higher cumulants observed → signature of CP?
- ▶ No conclusive results yet → Models needed!

This talk

- ▶ Ratios of net-proton number cumulants in the presence of CP
- ▶ Phenomenological approach → HRG model + critical fluctuations

Thermal baseline → Hadron resonance gas (HRG) model

- ▶ QCD pressure \sim Non-interacting gas of hadrons and resonances
→ No critical fluctuations

Coupling to critical mode fluctuations → No general prescription on modeling this effect

Phenomenological approach¹:

- ▶ Linear sigma models

$$m_p \sim m_0 + g\sigma$$

- ▶ σ fluctuations → Distribution function modified ($i = p, \bar{p}$)

$$f_i = f_i^0 + \delta f_i,$$

$$\delta f_i = \frac{\partial f_i}{\partial m_p} \delta m_p = -\frac{g}{T} \frac{m_p}{E} f_i^0 (1 - f_i^0) \delta \sigma ,$$

¹M. Bluhm et al., Eur. Phys. J. C 77, no. 4, 210 (2017)

*n*th order cumulant ($i = p, \bar{p}$):

$$C_n^i = VT^3 \frac{\partial^{n-1} (n_i/T^3)}{\partial (\mu_i/T)^{n-1}} \Big|_T ,$$

Net-proton number cumulants ($n = 1, \dots, 4$):

$$C_n = C_n^p + (-1)^n C_n^{\bar{p}} + (-1)^n \langle (V\delta\sigma)^n \rangle_c (m_p)^n (J_p - J_{\bar{p}})^n + \begin{pmatrix} \text{less singular} \\ \text{terms} \end{pmatrix}$$

$$J_i = \frac{gd}{T} \int \frac{d^3 k}{(2\pi)^3} \frac{1}{E} f_i^0 (1 - f_i^0)$$

Critical mode cumulants ($n \geq 2$) \rightarrow Universality

QCD \longleftrightarrow 3D Ising model

$$\sigma \longleftrightarrow M_I$$

$$(T, \mu) \longleftrightarrow (r, h)$$

$$\langle (V\delta\sigma)^n \rangle_c \propto \left. \frac{\partial^{n-1} M_I}{\partial h^{n-1}} \right|_r$$

Problem with this approach

$$C_2^{\text{sing.}} \sim \frac{\partial M_I}{\partial h} = \chi_I \longleftrightarrow \chi_{\text{chiral}} \text{ in QCD}$$

$$\chi_{\mu\mu}^{\text{sing.}} \approx C_2^{\text{sing.}} \sim \chi_{\text{chiral}}^{\text{sing.}} \Rightarrow \text{Too strong divergence of } C_2!$$

χ_{chiral} and $\chi_{\mu\mu}$ in the mean-field NJL model¹:

$$\chi_{\mu\mu} \simeq \chi_{\mu\mu}^{\text{reg}} + \sigma^2 \chi_{\text{chiral}}$$

Refined cumulants:

$$C_2 = C_2^p + C_2^{\bar{p}} + g^2 \sigma^2 \langle (V\delta\sigma)^n \rangle (J_p - J_{\bar{p}})^2$$

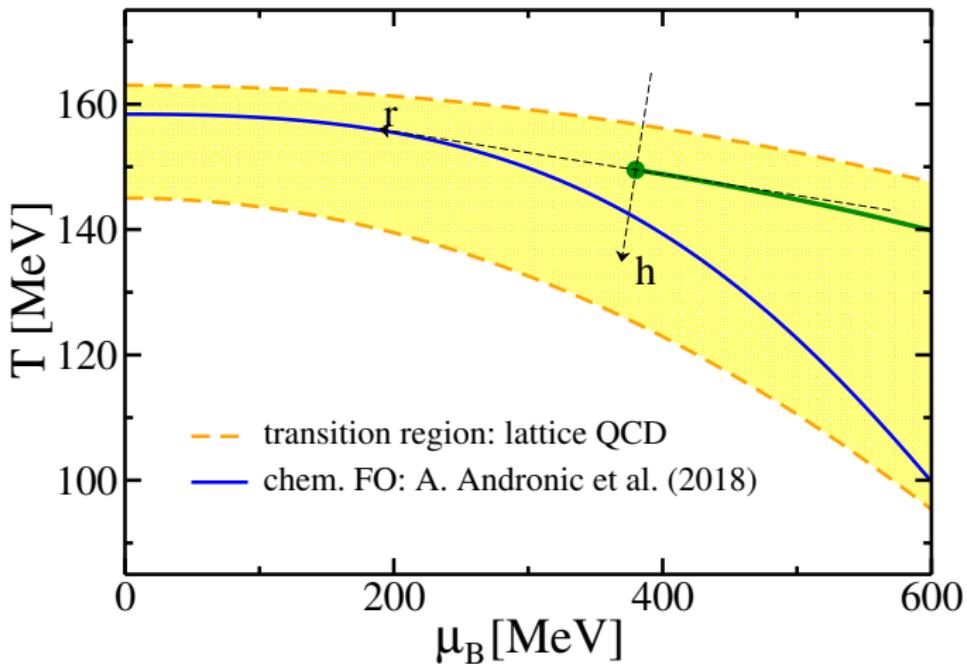

$$C_3 = C_3^p - C_3^{\bar{p}} - g^3 \sigma^3 \langle (V\delta\sigma)^n \rangle (J_p - J_{\bar{p}})^3$$

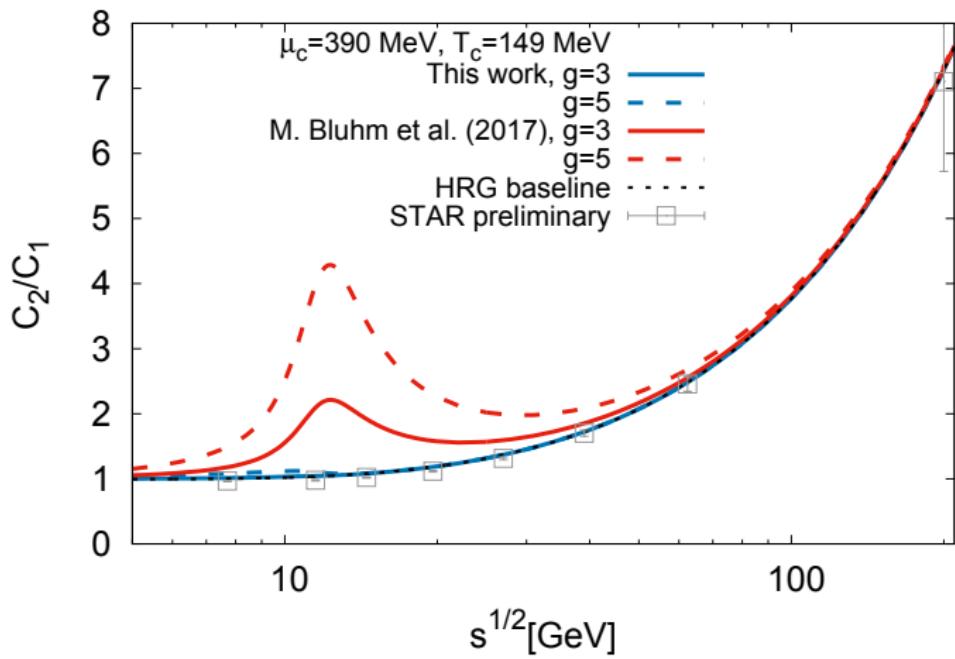

$$C_4 = C_4^p + C_4^{\bar{p}} + g^4 \sigma^4 \langle (V\delta\sigma)^n \rangle (J_p - J_{\bar{p}})^4$$

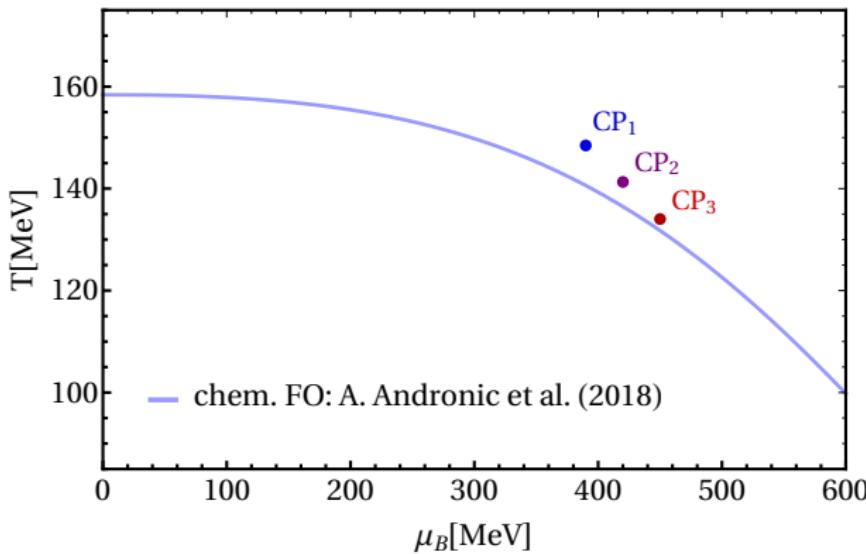

Cumulant ratios

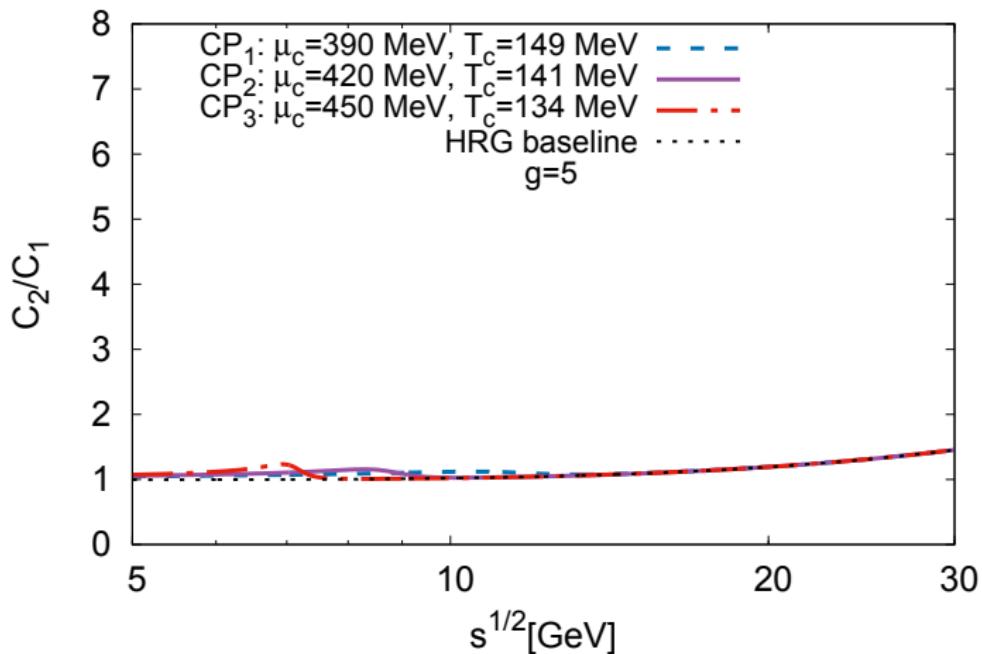

$$\frac{C_2}{C_1} = \frac{\sigma^2}{M}, \quad \frac{C_3}{C_2} = S\sigma, \quad \frac{C_4}{C_2} = \kappa\sigma^2,$$

Distance to the FO curve: CP₁ - farthest, CP₃ - closest

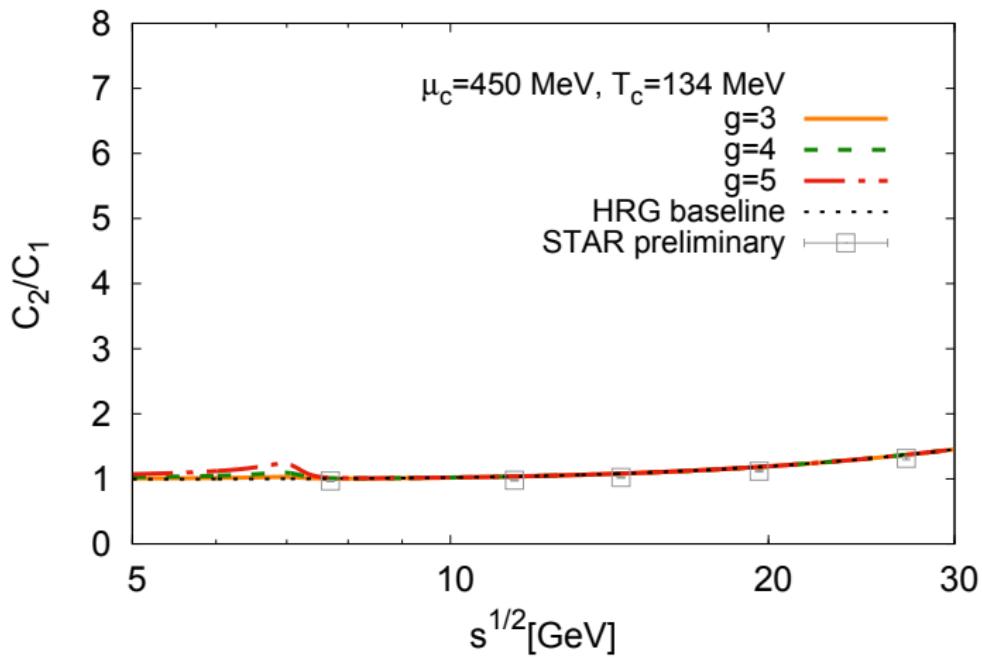

Distance to the FO curve: CP_1 - farthest, CP_3 - closest

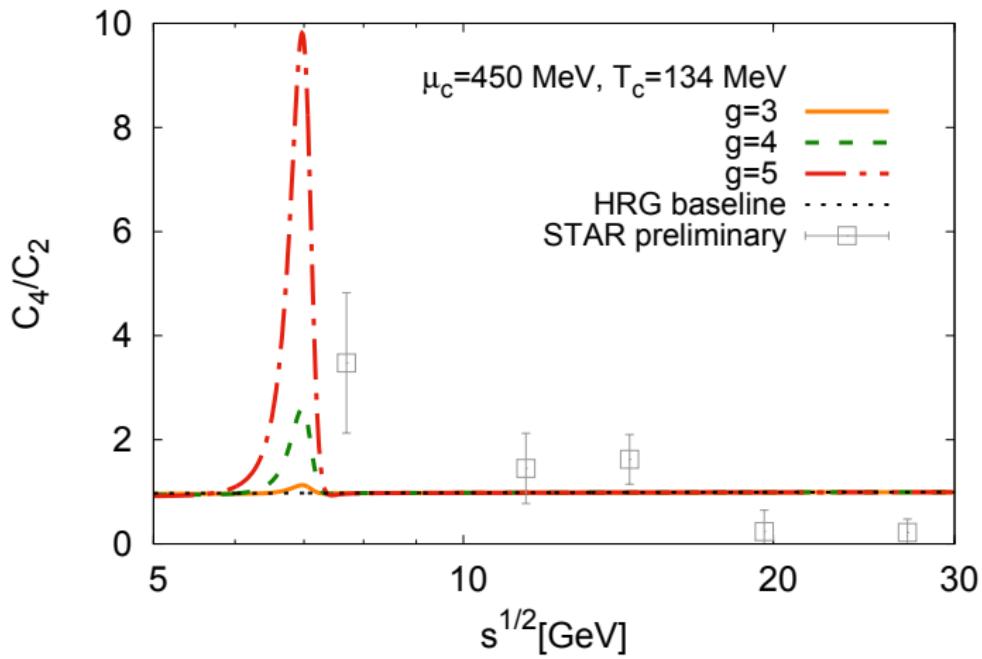

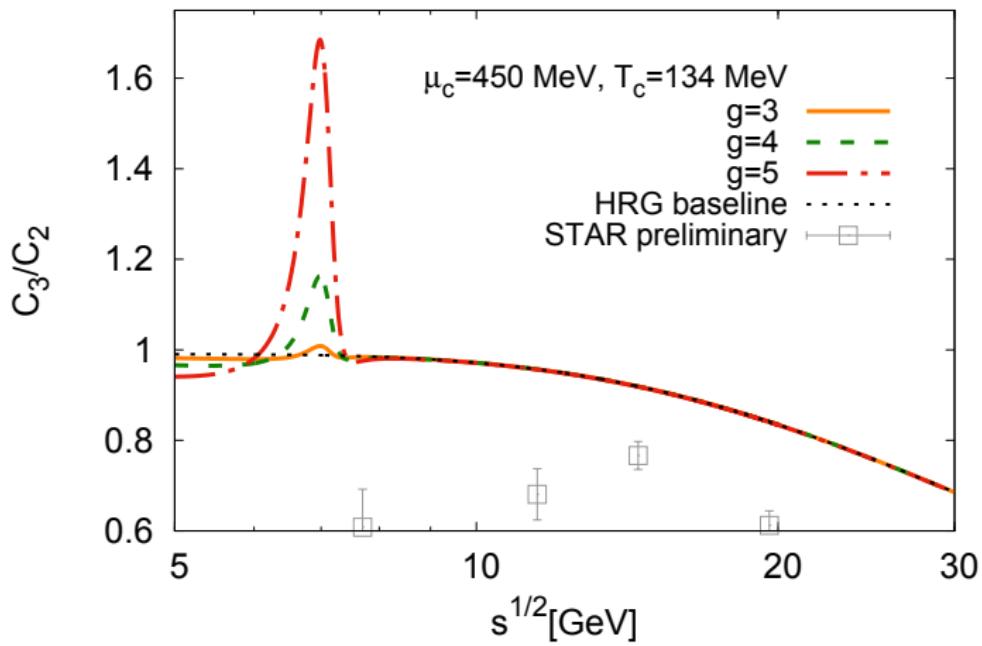

Distance to the FO curve: CP₁ - farthest, CP₃ - closest

CP_i	$\mu_{cp} [\text{MeV}]$	$T_{cp} [\text{MeV}]$
1	390	149
2	420	141
3	450	134

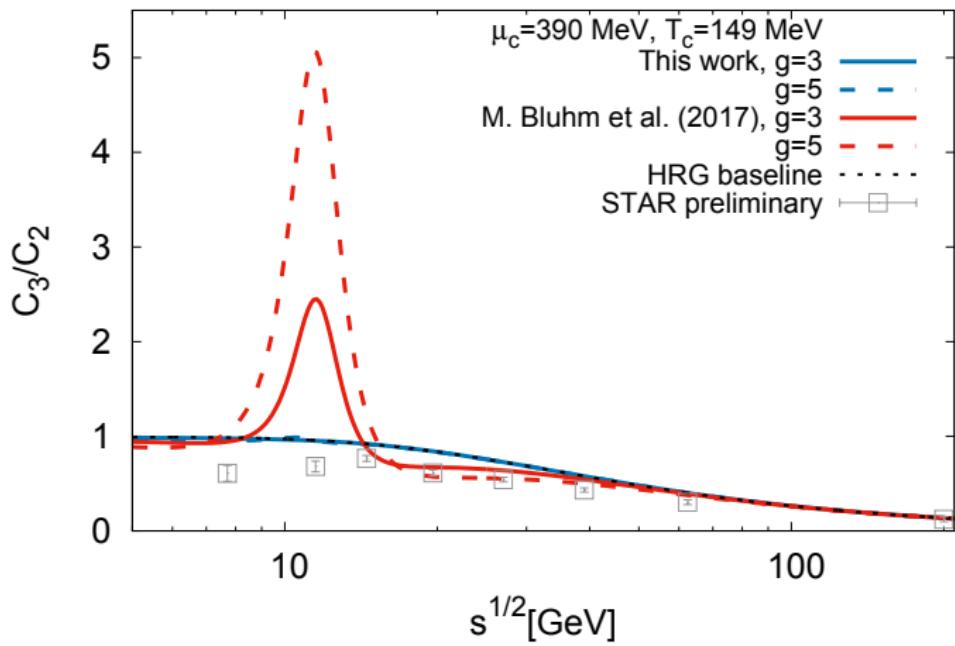

Conclusions:

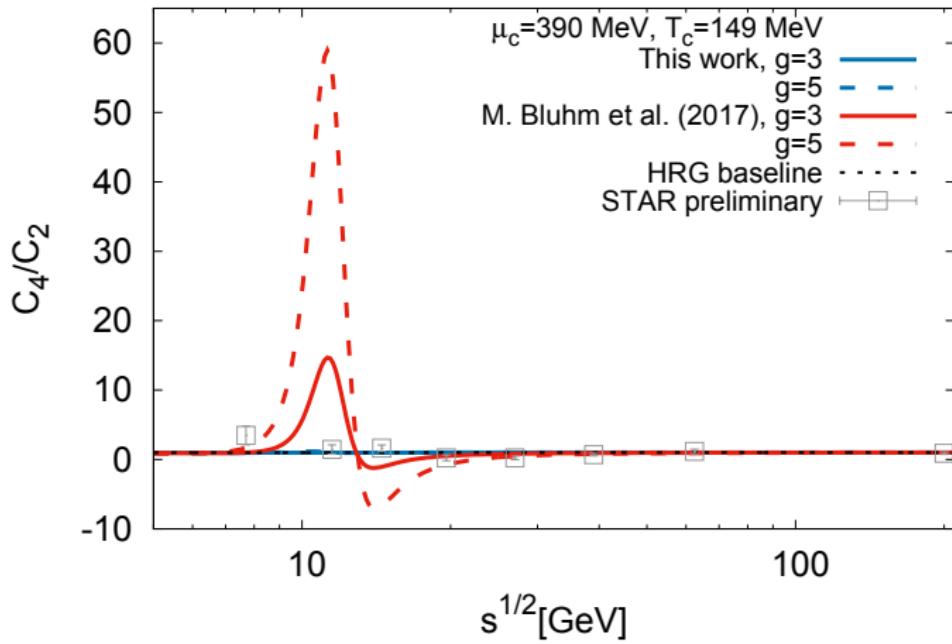

- ▶ This talk → ratios of net-proton number cumulants obtained with an effective model
- ▶ Identification of CP from the data → Need to know the systematics of cumulants expected from the Z_2 scaling
 - ▶ Systematics in the data \neq Systematics expected from Z_2
 - ▶ CP close to FO curve → Rather unlikely but more study needed
 1. Role of less critical contributions to cumulants¹
 2. Impact of resonance decays on net-proton number fluctuations²
 3. Out of equilibrium effects

Appendix

The recent¹ parametrization of chemical freeze-out conditions reads:

$$\mu_{fo}(\sqrt{s}) = \frac{a}{1 + 0.288\sqrt{s}}, \quad a = 1307.5 \text{ MeV}$$

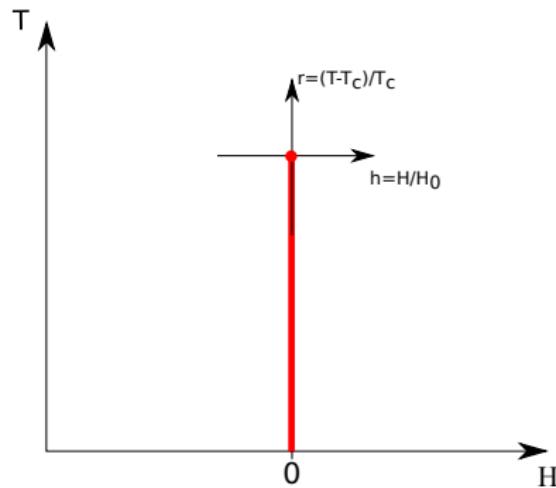

$$T_{fo}(\sqrt{s}) = \frac{T_{CF}^{lim}}{1 + \exp(2.60 - \ln(\sqrt{s})/0.45)}, \quad T_{CF}^{lim} = 158.4 \text{ MeV}$$

¹A. Andronic et al., Nature **561**, no. 7723, 321 (2018)

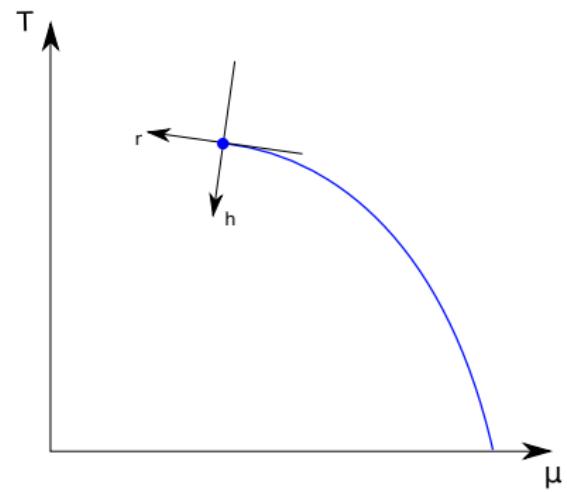

Mapping from QCD to the spin model phase diagram:

$$\tilde{r} = \frac{\mu_B - \mu_{cp}}{\Delta \mu_{cp}}, \quad \tilde{h} = \frac{T - T_{cp}}{\Delta T_{cp}},$$

Spin model

QCD

Spin model equation of state reads

$$M_I = M_0 R^\beta \theta$$

where (R, θ) is obtained from

$$\begin{aligned} r &= R(1 - \theta^2), \\ h &= R^{\beta\delta} w(\theta), \end{aligned}$$

β and δ are critical exponents and

$$w(\theta) = c\theta(1 + a\theta^2 + b\theta^4).$$
